

Malignancy label quality: the LSC bin has a ~40% false-positive rate

HSC_MPP is the node the central claim leans on most, and the highest-FPR bin inside the CCC graph (39.8%).
Lymphoid bins are clean (T_NK 3.6%, B_Plasma 7.7%); myeloid/primitive bins are not -- consistent with inferCNV keying on expression deviation (Stromal is higher at 90.3% but is excluded from the CCC graph by the established premise.)

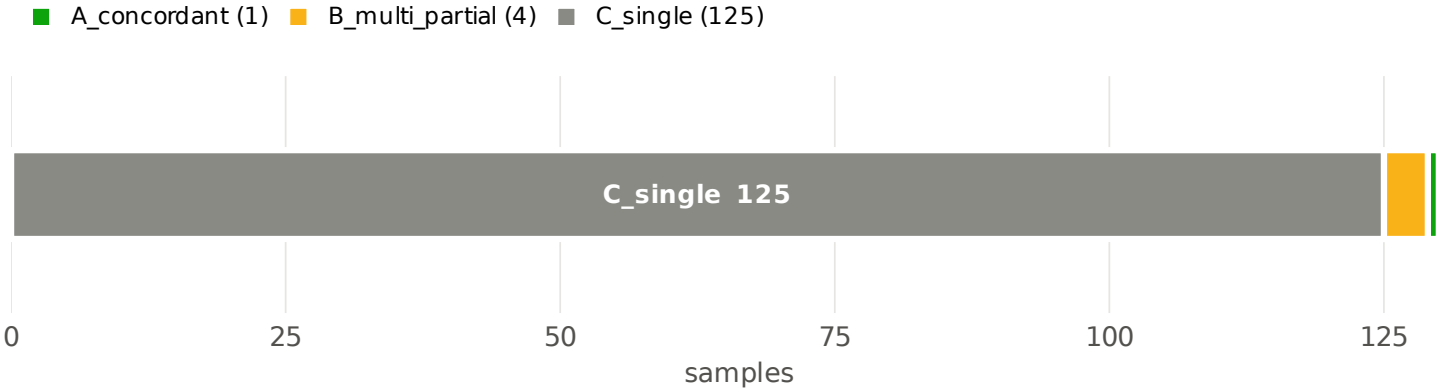

A Fraction of healthy-donor cells called malignant (false-positive rate)

Any malignant call in healthy marrow is by definition a false positive. Light grey = bins not in the CCC graph.

B Evidence-tier composition (130 samples)

Blueprint Phase 1 requires an inferCNV + Numbat + VarTrix consensus ($\geq 2/3$ agree);
in practice 125/130 are single-arm inferCNV. The 5 tier-A/B samples are all from GSE227903.
