

H1 (conserved emergent edges): no signal observed

0 of 49 edges pass the permutation test (min perm p = 0.052, min q = 0.87); all 5 blocks non-significant.

Key: edges come from CellChat and never pass through the malignancy labels -- so this null is immune to the label-quality problem, the

A AML-vs-healthy difference across the 49 directed edges

Colour = magnitude of the difference, but no cell survives the permutation test (all q >= 0.87). This is the structure of noise -- do not r

B BH-FDR q for the 5 pre-specified communication blocks (ordered by edge count)

All five blocks share the identical q = 0.93, far above 0.05.
