

H2 (topology carries disease information): significance is constructed, not topological

Both panels are deliberately designed falsification tests.

Conclusion: the current H2 signal cannot be attributed to network topology, nor to stemness.

A Alpha sweep: significance vanishes as the feature term is turned off

alpha=0 pure node features -> alpha=1 pure Gromov-Wasserstein (pure topology). Both models cross 0.05 at alpha=1.

B Feature decomposition (alpha=0.5): where the signal comes from

frac_malignant alone reproduces and amplifies the effect (beta=0.173 > all3's 0.075) -- it is forced to 0 for healthy samples at 01_build_fgw_inputs.R:67, so that separation is constructed. But dropping it still leaves beta=0.064 (p=0.001), of which only_ncells (cell count, a pure technical quantity) is beta=0.050 (p=0.008); only_stemness (the actual biological quantity) is not significant.
