

H3 (treatment-pressure axis): not interpreted -- dependent metadata fields are unverified

WARNING: every conclusion here rests on the timepoint (Dx/MRD/Relapse) and patient-pairing fields, both known to disagree with the source papers in several datasets (the reconciliation table does not exist yet; 87 more samples have an empty timepoint field). Until verified, the V-shape can be neither confirmed nor denied.

A Stemness signatures along the treatment axis (transcriptional, independent of projection)

Blueprint H3 predicts monotone Dx < MRD < Relapse. Actual: only 2 of 4 signatures are V-shaped (vanGalen_HSC_like peaks at MRD, HSPC_core declines monotonically). These are cell-level pooled means (Dx/MRD/Relapse: 4,136 / 8,634 / 1,653 malignant cells): 62% of MRD malignant cells come from one patient (6323), so the 'V' may be a single-sample effect.

B Within-pair median change (bold = p<0.05)

The three comparisons use different patient sets (n=6 / 5 / 6; only 5 have all three timepoints), so the third bar is not the sum of the first two. All from the single dataset GSE227903.
